What this means:

- Audio characteristics don't explain everything: no single audio feature strongly explains popularity ($R^2 \approx 0.06$ on a linear regression); one can wonder whether artist fame or marketing play a bigger role, though this dataset cannot demonstrate it.
- The sound of hits has changed: average energy declines steadily (76.6 → 62.8) while danceability climbs sharply from 2017 onward; chart pop has become more danceable and less "energetic" in the raw sense.
- Dance pop dominates: 36% of charted tracks belong to this single genre, well ahead of pop (5.7%) and Atlanta hip hop (3.9%).
- Energy and loudness are strongly linked ($r = 0.71$), which makes acoustic sense, but worth keeping in mind so as not to treat these two variables as independent signals in a model.
